

*Remark (\*)*. Any substitution, in particular  $\sigma$ , only changes a finite number of variables. Furthermore a result of a run of the unification algorithm is acyclic in the sense that if a substitution  $u \mapsto t$  is added to the resulting substitution, it is never the case that at a later stage  $t \mapsto u$  is added. This can easily be seen by considering that at the point when  $u \mapsto t$  is added to the resulting substitution, every occurrence of  $u$  is replaced by  $t$ , so  $u$  is not encountered by the algorithm at a later stage.

Therefore in order to show that a statement holds for every  $u \mapsto t$  in a unifier  $\sigma$ , it suffices to show by an induction argument that for every substitution  $v \mapsto s$  which is added to the resulting unifier by the unification algorithm that it holds for  $v \mapsto s$  under the assumption that it holds for every  $w \mapsto r$  such that  $w$  occurs in  $s$  and  $w \mapsto r$  is added to the resulting substitution at a later stage.  $\triangle$

**Conjecture 1.** *Let  $C$  be a clause in a resolution refutation. Suppose that  $\text{AI}^\Delta(C)$  contains a maximal  $\Gamma$ -term  $\gamma_j[z_i]$  which contains a lifting variable  $z_i$ . Then  $z_i <_{\hat{\mathcal{A}}(C)} y_j$ .*

*Proof.* We proceed by induction. For the base case, note that no multicolored terms occur in initial clauses, so no lifting term can occur inside of a  $\Gamma$ -term.

Suppose a clause  $C$  is the result of a resolution of  $C_1 : D \vee l$  and  $C_2 : E \vee \neg l$  with  $l\sigma = l'\sigma$ . Furthermore suppose that for every lifting term inside a  $\Gamma$ -term in the clauses  $C_1$  and  $C_2$  of the refutation, for every term of the form  $\gamma_j[z_i]$  we have that  $z_i <_{\hat{\mathcal{A}}(C_1)} y_j$  or  $z_i <_{\hat{\mathcal{A}}(C_2)} y_j$  respectively. Hence there is an arrow  $(p_1, p_2)$  in  $\hat{\mathcal{A}}(C_1)$  or  $\hat{\mathcal{A}}(C_2)$  such that  $z_i$  is contained in  $P(p_1)$  and  $z_j$  is contained in  $P(p_2)$ . In  $\text{AI}^\Delta(C)$ ,  $P(p_1)$  contains  $\ell[z_i\sigma]\tau = z_i\tau$  and  $P(p_2)$  contains  $\ell[z_j\sigma]\tau = z_j\tau$ . Hence the indices of the lifting variables might change, but this renaming does not affect the relation of the objects as  $\hat{\mathcal{A}}(C_1) \cup \hat{\mathcal{A}}(C_2) \subseteq \hat{\mathcal{A}}(C)$ .

We show that  $z_i <_{\hat{\mathcal{A}}(C)} z_j$  holds true also for every new term of the form  $\gamma_j[z_i]$  for some  $j, i$  in  $\text{AI}^\Delta(C)$ . By “new”, we mean terms which are not present in  $\text{AI}^\Delta(C_1)$  or  $\text{AI}^\Delta(C_2)$ . Note that new terms in  $\text{AI}^\Delta(C)$  are of the form  $\ell_{\Delta, x}[t\sigma]\tau$  for some  $t \in \text{AI}^\Delta(C_1) \cup \text{AI}^\Delta(C_2)$ . By Lemma ??,  $\sigma$  does not introduce lifting variables. Hence a new term of the form  $\gamma_j[z_i]$  is created either by introducing a  $\Delta$ -term into a  $\Gamma$ -term or by introducing  $\gamma_j[\delta_i]$  via  $\sigma$ , both followed by the lifting. Note that  $\tau$  only substitutes lifting variables by other lifting variables and hence does not introduce lifting variables. Furthermore by Lemma ??,  $\tau$  only substitutes lifting variables for other lifting variables, whose corresponding term is more specialised. Hence if there exists an arrow from a lifting variable to  $\gamma_j[z_i]$  according to this lemma, it is also an appropriate arrow if  $\gamma_j[z_i]$  is replaced by  $\gamma_j[\delta_i]\tau$ .

We now distinguish the two cases under which a new term  $\gamma_j[z_i]$  can occur in  $\text{AI}^\Delta(C)$ :

**Suppose for some  $\Gamma$ -term  $\tilde{\gamma}_j[u]$  in  $\text{AI}^\Delta(C_1)$  or  $\text{AI}^\Delta(C_2)$ ,  $(\tilde{\gamma}_j[u])\sigma = \gamma_j[\delta_i]$  for some  $i$ .**

The substitution can also introduce a grey term containing a delta term, make sure to handle that!

The substitution can also introduce a gamma term containing a delta term, make sure to handle that!

TODO: continue here as soon as arrow pos issue is sorted out

**Suppose for some variable  $v$  in  $\text{AI}^\Delta(C_1)$  or  $\text{AI}^\Delta(C_2)$ ,  $v\sigma = \gamma_j[\delta_i]$  for some  $i$ .**

As  $v$  is affected by the unifier, it occurs in the literal being unified, say w.l.o.g. in  $l$  in  $C_1$ . At some well-defined point in the unification algorithm,  $v$  is substituted by an abstraction of  $\gamma_j[\delta_i]$ . Let  $p$  be the position of the occurrence of  $v$  in  $l$  which causes this substitution. Furthermore, let  $p'$  be the position corresponding to  $p$  in  $l'$ .

Note that any arrow from or to  $p'$  also applies to  $p$  in  $\hat{\mathcal{A}}(C)$  and hence to  $\gamma_j[z_i]$  as they are merged due to occurring in the resolved literal. So it suffices to show that there is an arrow from an appropriate lifting variable to  $p'$ . We denote the term at  $p'$  by  $t$ .

Note that  $t\sigma = \gamma_j[\delta_i]$ . So  $t$  is either a  $\Gamma$ -term containing a  $\Delta$ -term, in which case we know that there is an appropriate arrow by the induction hypothesis as  $t$  occurs in  $l'$  in  $C_2$ , or  $t$  is an abstraction of  $\gamma_j[\delta_i]$ , in which case we can assume the existence of an appropriate arrow by Remark (\*). □
